IBM Environmental Intelligence Suite:

To derive business insights, IBM has developed a product-based cloud platform with SaaS (Software as a Solution) platform to combine geospatial, weather, environment IOT data where we are able to monitor the status and performance with service locations by using dashboards, maps, charts, and alerts.

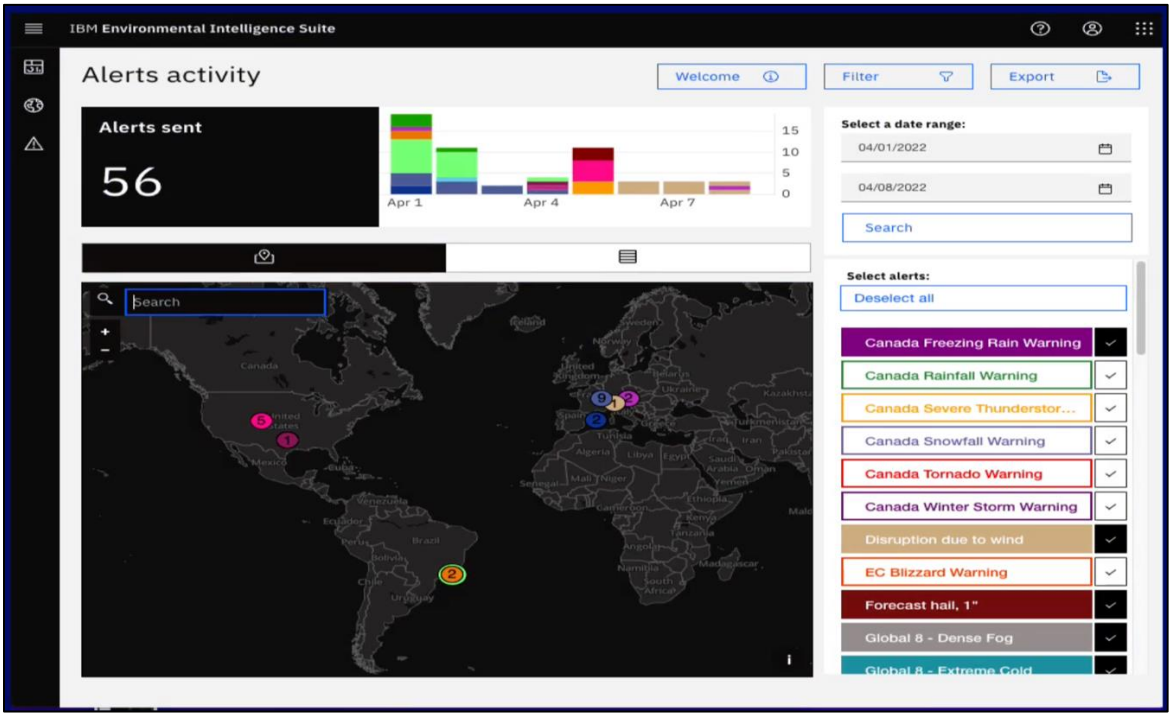

Other components of IBM Environmental Intelligence Suite:

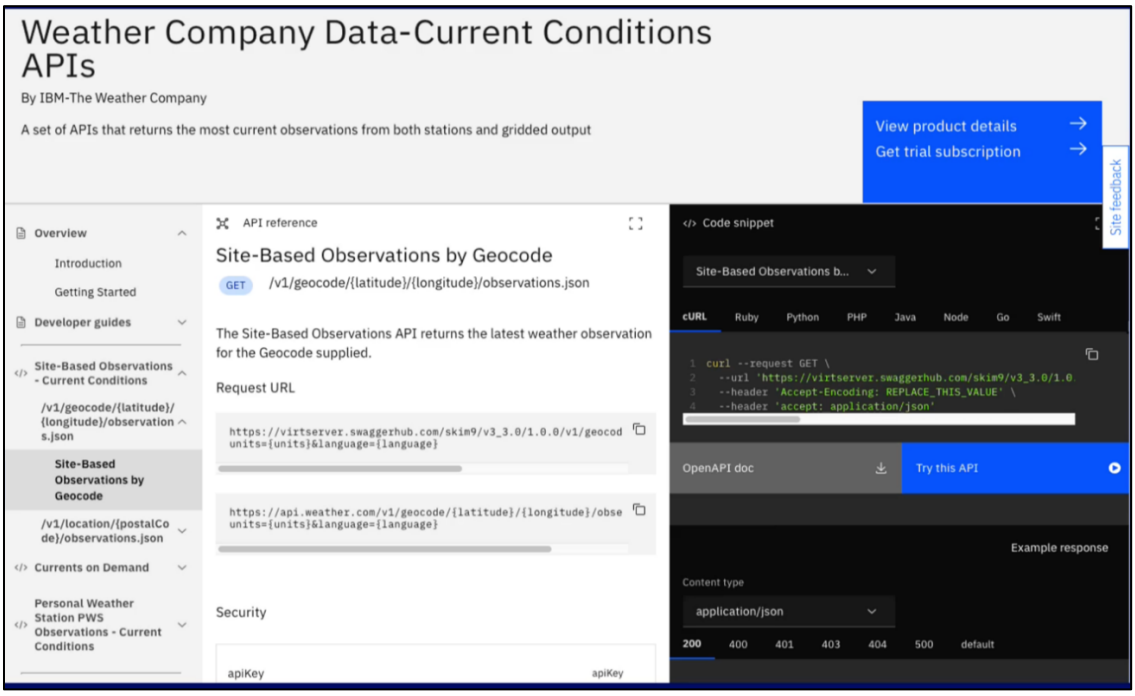

a. Dashboard Visualization – It has the capability to provide weather visualizations for locations, along with an interactive map.

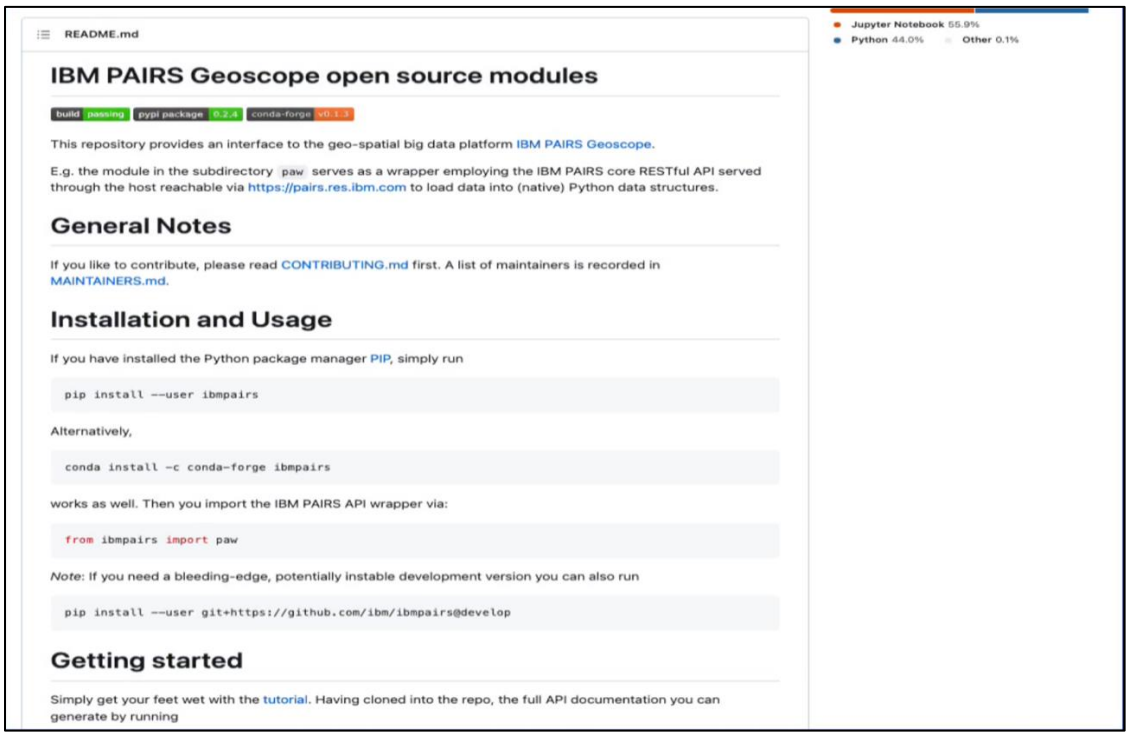

b. Alert Console – Manages and monitors weather events such as temperature, rainfall, and wind conditions.

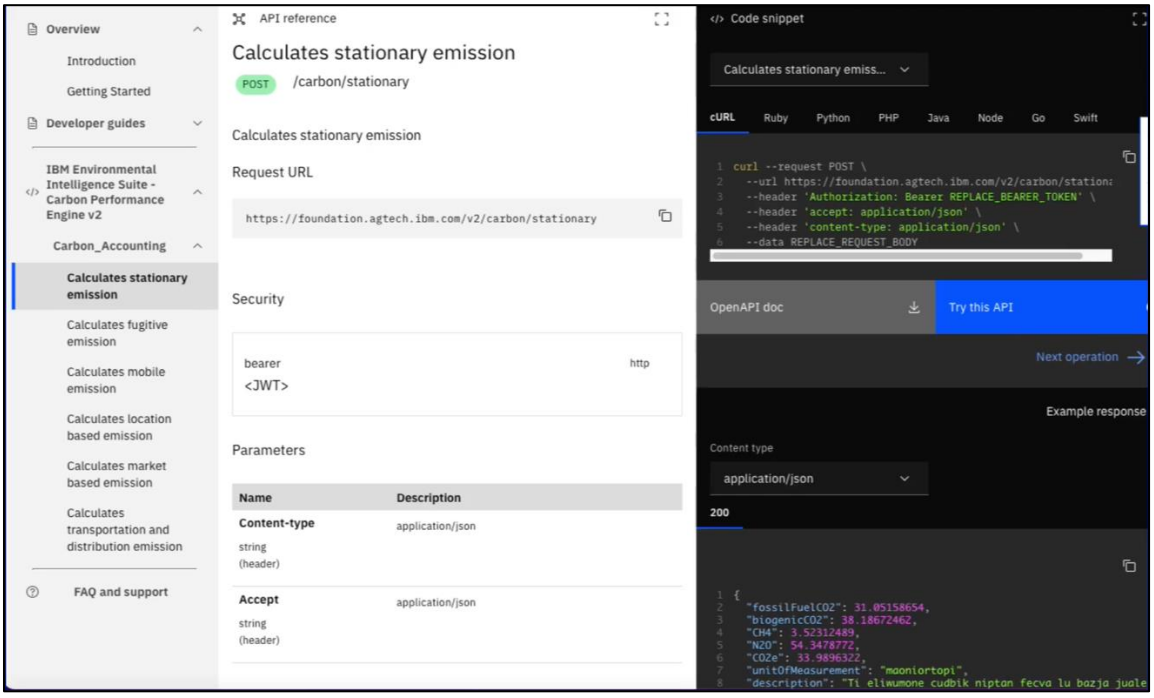

c. Weather data API – Queries current and forecasted conditions, seasonal and sub seasonal forecasts, severe weather events, and historical weather data for analysis.

d. Geospatial Analytics – An analytics engine for geospatial-temporal data , used or conducting queries to reveal key relationships between layers of data.

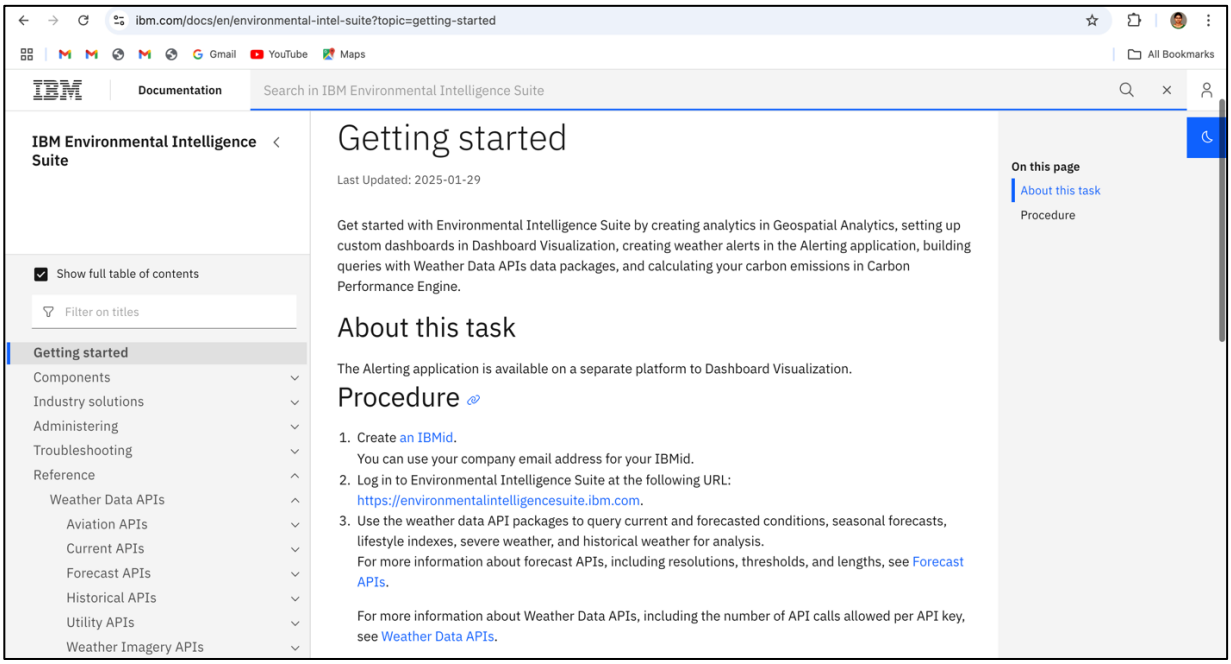

e. Carbon performance engine – Supports sustainability efforts by using the Carbon Accounting API to manage internal and supply chain emissions.

More closely aligned with our project, this Environmental Intelligence Suite can be useful for businesses to understand the impact of weather through temperature predictions.

To get hands-on with the Environmental Intelligence Suite, we attempted to explore the Weather Data API using the procedure outlined below

Additionally, to gain access to a rich set of weather data sources, daily forecasts, and historical weather data, we can make Weather Data API calls by using an API key, adhering to open API standards. The API can be integrated with applications and business processes to enable data-driven decisions.

We have access to different APIs like Aviation API, Current API, Forecast API, Historical API, Utility API, and Weather Imagery API.

We explored the Forecast APIs to obtain weather data related to forecasted conditions such as time-based forecasts, temperature, precipitation, and forecast data for analytical tooling.

In our case, the forecasting APIs most closely aligned with our requirements are:

a. Daily Forecast API – This API being sourced from Weather Company Forecast System has the capability to return weather forecasts starting from the current day determining the number of days returned in API response.
b. Forecast Data for Analytical Tooling API – This API has the capability to provide aggregated forecast data, useful for performing predictive analytics in project work.
